CodeGraph

A graph based multi-agent development workspace

A working local experiment that maps application modules, agent roles, file ownership, and validation evidence.

Built to explore the idea, not to claim general autonomous development.

Software work has structure. The agent workflow should show it.

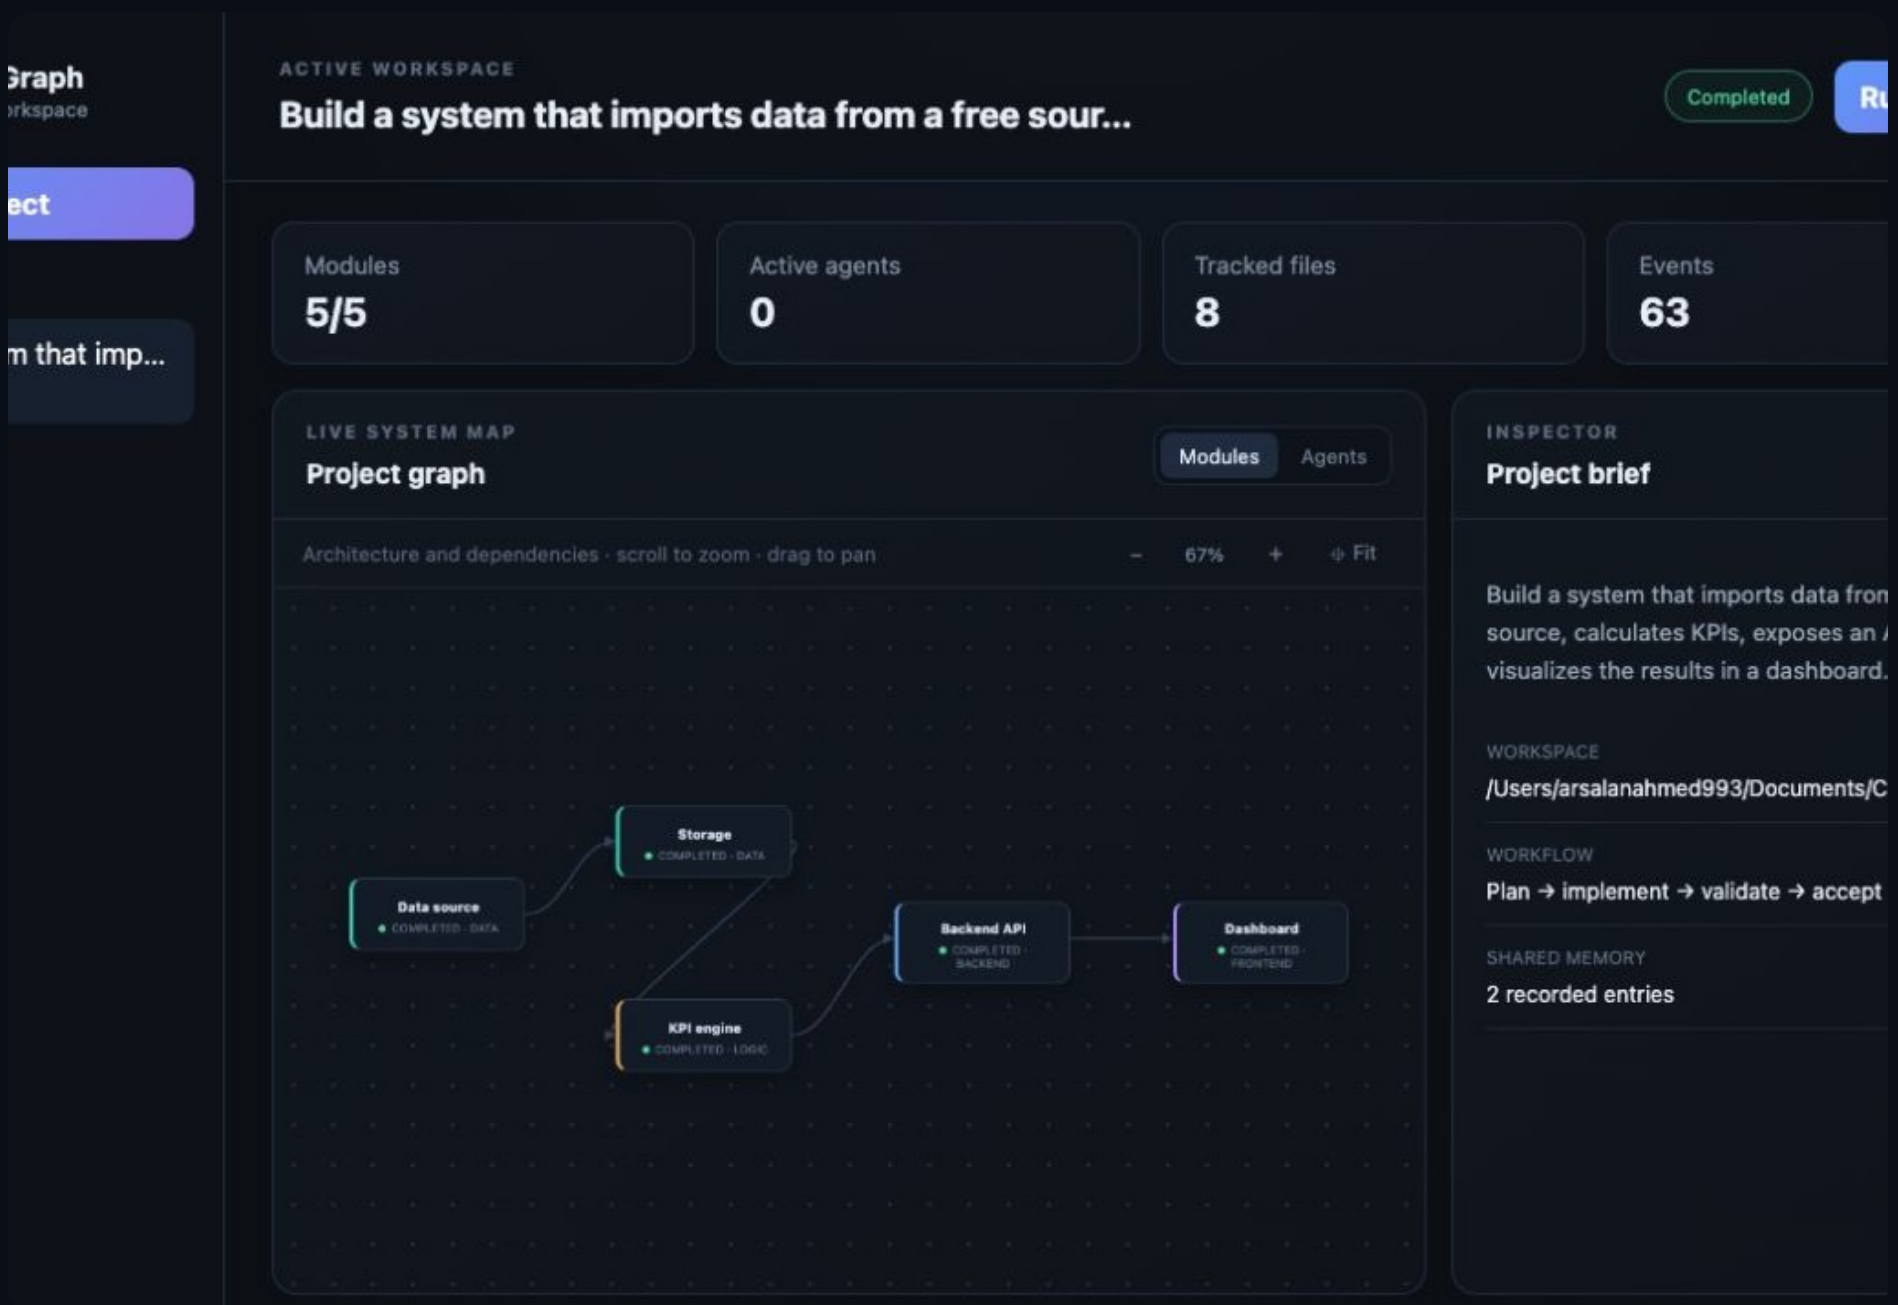

A request becomes connected modules with clear dependencies. Each module gets an owner, focused tasks, and visible checks.

PROJECT REQUEST

Module graph
Agent graph
Shared memory
Validation history

The application becomes a living dependency map

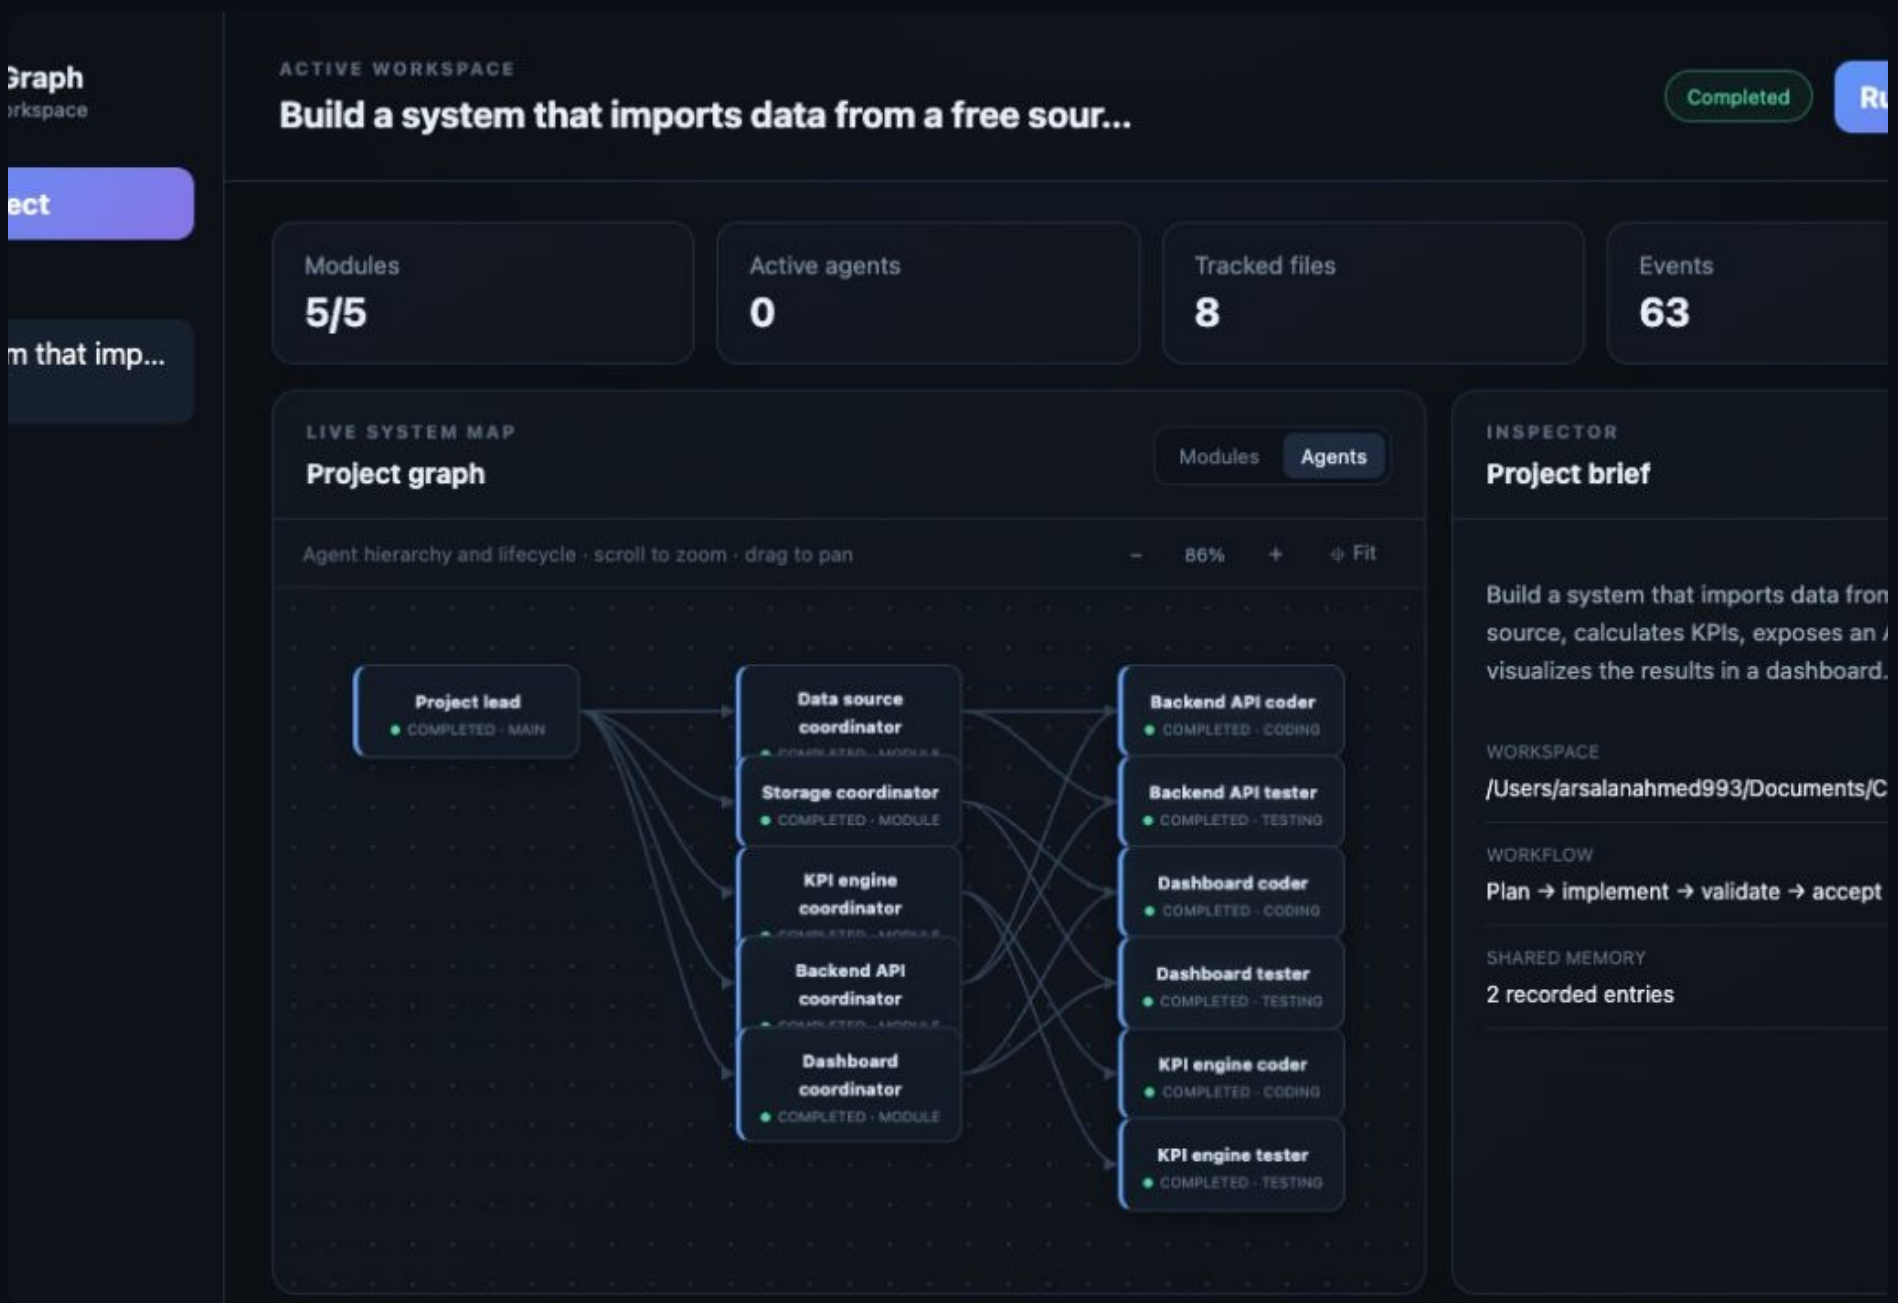

Modules show ownership, status, and how data moves through the project.

Zoom, pan, inspect, and watch the graph change as features are added.

Every active role stays visible

The project lead coordinates module owners. Coding and testing agents handle focused work and publish results back to the project.

Agent creation, progress, completion, failure, and cancellation appear in the event stream.

Generated code needs evidence before acceptance

The orchestration layer controls file access and keeps changes inside the project workspace.

01 **Compile the source**

02 **Run automated tests**

03 **Record files, hashes, and results**

A failed check blocks the module and returns useful diagnostics to the workflow.

A focused experiment with a working end-to-end loop

Python and SQLite power the local engine. The browser dashboard uses plain JavaScript. A deterministic demo provider lets the workflow run without paid model access.

Current boundary

One generated application pattern and sequential module execution

Next experiment

Constrained model-generated patches behind the same validation gate
